

# Longest Substring with Same Letters after Replacement (hard)

## We'll cover the following

- Problem Statement
- Try it yourself
- Solution
- Code
  - Time Complexity
  - Space Complexity

## Problem Statement

Given a string with lowercase letters only, if you are allowed to **replace no more than 'k' letters** with any letter, find the **length of the longest substring having the same letters** after replacement.

### Example 1:

Input: String="aabccbb", k=2

Output: 5

Explanation: Replace the two 'c' with 'b' to have a longest repeating substring "bbbbbb".

### Example 2:

Input: String="abbcb" k=1  
Output: 4

Explanation: Replace the 'c' with 'b' to have a longest repeating substring "bbbb".

### Example 3:

Input: String="abccde", k=1

Output: 3

Explanation: Replace the 'b' or 'd' with 'c' to have the longest repeating substring "ccc".

## Try it yourself

Try solving this question here:

Java

Python3

JS

C++

```
class CharacterReplacement {  
    public static int findLength(String str, int k) {  
        // TODO: Write your code here  
        return -1;  
    }  
}
```

## Solution

This problem follows the **Sliding Window** pattern and we can use a similar dynamic sliding window strategy as discussed in No-repeat Substring (<https://www.educative.io/collection/page/5668639101419520/567146485435596>) We can use a HashMap to count the frequency of each letter.

≡  (/learn) 

We'll iterate through the string to add one letter at a time in the window. We'll also keep track of the count of the maximum repeating letter in any window

---

(let's call it `maxRepeatLetterCount` ). So at any time, we know that we can have a window which has one letter repeating `maxRepeatLetterCount` times, this means we should try to replace the remaining letters. If we have more than 'k' remaining letters, we should shrink the window as we are not allowed to replace more than 'k' letters.

## Code

Here is what our algorithm will look like:

**Java**

Python3

C++

JS

```
import java.util.*;

class CharacterReplacement {

    public static int findLength(String str, int k) {
        int windowStart = 0, maxLength = 0, maxRepeatLetterCount = 0;
        Map<Character, Integer> letterFrequencyMap = new HashMap<>();
        // try to extend the range [windowStart, windowEnd]
        for (int windowEnd = 0; windowEnd < str.length(); windowEnd++) {
            char rightChar = str.charAt(windowEnd);
            letterFrequencyMap.put(rightChar, letterFrequencyMap.getOrDefault(rightChar, 0) + 1);
            maxRepeatLetterCount = Math.max(maxRepeatLetterCount, letterFrequencyMap.get(rightChar));

            // current window size is from windowStart to windowEnd, overall we have a letter which is
            // repeating 'maxRepeatLetterCount' times, this means we can have a window which has at most
            // repeating 'maxRepeatLetterCount' times and the remaining letters we should not have more
            // if the remaining letters are more than 'k', it is the time to shrink the window from the
            // left so that the remaining letters are not allowed to replace more than 'k' letters
            if (windowEnd - windowStart + 1 - maxRepeatLetterCount > k) {
                char leftChar = str.charAt(windowStart);
                letterFrequencyMap.put(leftChar, letterFrequencyMap.get(leftChar) - 1);
                windowStart++;
            }

            maxLength = Math.max(maxLength, windowEnd - windowStart + 1);
        }

        return maxLength;
    }

    public static void main(String[] args) {
        System.out.println(CharacterReplacement.findLength("aabccbb", 2));
        System.out.println(CharacterReplacement.findLength("abbcb", 1));
        System.out.println(CharacterReplacement.findLength("abccde", 1));
    }
}
```

## Time Complexity

The time complexity of the above algorithm will be  $O(N)$  where 'N' is the number of letters in the input string.

## Space Complexity

educative (learn)

As we are expecting only the lower case letters in the input string, we can conclude that the space complexity will be  $O(26)$ , to store each letter's frequency in the **HashMap**, which is asymptotically equal to  $O(1)$ .
